Machine learning in Combinatorial Optimization January 21, 2021

A combinatorial optimization problem A is a quadruple (I, f, m, g), where:

- *I* is a set of instances;
- given an instance $x \in I$, f(x) is the finite set of feasible solutions;
- given an instance x and a feasible solution y of x, m(x, y) denotes the measure of y, which is
 usually a positive real.
- g is the goal function, and is either min or max.

The goal is then to find for some instance x an <u>optimal solution</u>, that is, a feasible solution y with $m(x, y) = g\{m(x, y')|y' \in f(x)\}$

Without loss of generality, any CO problem can be formulated as a constrained min-optimization program.

Machine Learning

"Field of study that gives computers the ability to learn without being explicitly programmed." Machine learning definition by Arthur Samuel.

Machine learning approaches:

- Supervised learning
- Unsupervised learning
- Reinforcement learning

Machine learning in Combinatorial Optimization

January 21, 2021

Supervised vs Unsupervised learning

Supervised learning

a set of input (features) / target pairs is provided and the task is to find a function that for every input has a predicted output as close as possible to the provided target.

Unsupervised learning

one does not have targets for the task one wants to solve, but rather tries to capture some characteristics of the joint distribution of the observed random variables.

Input data Prediction Its an 0 apple! Annotations Mode These are apples unsupervised learning Input data Mode

supervised learning

Reinforcement learning

an agent interacts with an environment through a Markov decision process (MDP) in order to maximize the notion of cumulative reward.

Discrete-time Markov chain

a sequence of random variables $X_1, X_2, X_3, ...$ with the Markov property: $Pr(X_{n+1} = x | X_1 = x_1, X_2 = x_2, ..., X_n = x_n) = Pr(X_{n+1} = x | X_n = x_n)$

Heuristics

Heuristic

is any approach to problem solving or self-discovery that employs a practical method that is not guaranteed to be optimal, perfect, or rational, but is nevertheless sufficient for reaching an immediate, short-term goal or approximation. Where finding an optimal solution is impossible or impractical, heuristic methods can be used to speed up the process of finding a satisfactory solution.

Minimum Vertex Cover (MVC)

Minimum Vertex Cover

Given a graph G, find a subset of nodes $S \subseteq V$ such that every edge is covered, i.e. $(u, v) \in E \Leftrightarrow u \in S$ or $v \in S$, and |S| is minimized.

MVCApprox iteratively selects an uncovered edge and adds both of its endpoints.

MVCApprox-Greedy, that greedily picks the uncovered edge with maximum sum of degrees of its endpoints.

| Instance | OPT | S2V-DQN | MVCApprox | MVCApprox-Greedy |
|------------------------|-----|---------|-----------|------------------|
| full MemeTracker graph | 473 | 474 | 666 | 578 |
| Approx. ratio | 1 | 1.002 | 1.408 | 1.222 |

Maximum Cut

Given a graph *G*, find a subset of nodes $S \subseteq V$ such that the weight of the cut-set $\sum_{(u,v)\in C} w(u,v)$ is maximized, where cut-set $C \subseteq E$ is the set of edges with one end in *S* and the other end in $V \setminus S$.

MaxcutApprox, which maintains the cut set $(S, V \setminus S)$ and moves a node from one side to the other side of the cut if that operation results in cut weight improvement. To make MaxcutApprox stronger, we greedily move the node that results in the largest improvement in cut weight.

| Instance | OPT | S2V-DQN | MaxcutApprox | SDP |

RL: Learning methods

Demonstration

the policy is trained to reproduce the action of an expert policy by minimizing some discrepancy in the action space.

Experience

When learning through the experience, no expert is involved; only maximizing the expected sum of future rewards (the return) matters.

$$Decision? \xrightarrow{\hat{\pi}_{ml}} action \xrightarrow{score} reward \qquad max return$$

End to end learning

train the ML model to output solutions directly from the input instance.
